## 1. Talk I by Lin: the big picture

 $\dots$  once we could merely formulate Fargues' conjecture, enough mathinery is available to apply Lafforgue's ideas to get the "automorphic-to-Galois" direction...

[FS21, Sect. I.11]

## 1.1. What is the local Langlands correspondence?

**Notation 1.1.1.** We fix the following notations:

- E is a local field (e.g. ...  $\mathbb{R}, \mathbb{C}, \mathbb{Q}_p, \mathbb{F}_p((t)))^1$ ;
- G is a reductive group over E;
- $\hat{G}$  is the Langlands dual group over  $\mathbb{Z}$ ;
- $W_E$  is the Weil group for E.

## Conjecture 1.1.2. There is a canonical map between sets:

$$\left\{irreducible\ objects\ \operatorname{Rep}_{\mathbb{C}}(G(E))\right\} \to \left\{W_E \to \hat{G}(\mathbb{C})\right\},\ \pi \mapsto \varphi_{\pi}$$

 $subject\ to\ certain\ compatibilities.$ 

## Remark 1.1.3. Several remarks are in order.

- (0) In general this is not a bijection.
- (1) From easy to hard: archimedean, char p nonarchimedean, char 0 nonarchimedean. E.g., the conjecture is unknown for  $E = \mathbb{Q}_p$  and general redcutive group.
- (2) G(E) is a topological group and we require  $\pi$  to be smooth, i.e., any vector is fixed by some compact open subgroup.

Notes taken by Lin.

 $<sup>^{1}</sup>$ The colors are chosen to be compatible with [SW20, Figure 12.1].

(3)  $W_E$  is a modification of  $\operatorname{Gal}(\overline{E/E})$ .  $W_{\mathbb{C}} = \mathbb{C}^{\times}$ ,  $W_{\mathbb{R}}$  is the canonical extension of  $\operatorname{Gal}(\mathbb{C}/\mathbb{R})$  by  $\mathbb{C}^{\times}$ . For nonarchimedean E with residue field  $k = \mathbb{F}_q$ ,

The necessity of  $W_E$  instead of  $Gal(\overline{E}/E)$  can be already seen in local class field theory.

- (4)  $W_E$  is a topological group and we require  $\varphi_{\pi}$  to be continuous. However, it is not equipped with the subspace topology from  $Gal(\overline{E}/E)$ . Instead,  $I_E$  has the subspace topology from  $Gal(\overline{E}/E)$ , which is pro-finite, and is forced to be open in  $W_E$ , which is therefore locally pro-finite.
- (5)  $\varphi_{\pi}$  is the so-called L-parameter of  $\pi$ .
- (6) Part of the compatible requirements are about L-functions and ε-factors. Lin knows nothing about them. Maybe someone can explain later?

### 1.2. What is geometrization?

**Answer 1.2.1.** Do global geommetric Langlands on the Fargues–Fontaine curve, which behaves like a genus 0 curve in nonarchimedean geometry.

To explain what this mean, we need some basic notions in analytic geometry.

**Notation 1.2.2.** From now on, we restrict to the case  $E = \mathbb{Q}_p$ . There is no essential difference for general E, and the char p case is even easier.

**Analogy 1.2.3.** Tutorials on analytic geometry will be provided by Lin and Yuchen in the next weeks. For now, let us be satisfied by the following:

	algebraic geometry	$analytic \ geometry$
affine	Fine Spec $R, R \in CAlg$ Spa $(R, R^+)$ ,	
		$(R, R^+)$ is a Huber pair: $R^+ \subset R \in \text{CAlg}(\text{Top})$
		$satisfying\ certain\ conditions$
globalization	scheme	(pre-)adic space
	as locally ringed spaces	as locally topologically ringed spaces
point	$\operatorname{Spec} K, K \text{ is a field}$	$\operatorname{Spa}(K, K^+), (K, K^+)$ is an affinoid field
		analytic if $K$ is nondiscrete
		nonanalytic if $K$ is discrete

**Notation 1.2.4.** In most cases, people make the canonical choice  $R^+ := R^\circ$  being the subring of power-bounded elements and write  $\operatorname{Spa} R := \operatorname{Spa}(R, R^\circ)$ .

Remark 1.2.5. Among all the (pre)-adic spaces, there is a class of objects, called perfectoid spaces, that are well-adapted to connect char 0 and char p. Affine perfectoid spaces are given by  $\operatorname{Spa}(R, R^+)$  such that R is a perfectoid ring. Basic examples of perfectoid rings include  $\mathbb{F}_p((t^{1/p^\infty}))$ , which is the completion of  $\bigcup_n \mathbb{F}_p((t))(t^{1/p^n})$ , and  $\mathbb{Q}_p^{\operatorname{cycl}}$ , which is the completion of  $\mathbb{Q}_p(\mu_{p^\infty})$ . Any perfectoid ring is defined over  $\mathbb{Z}_p$  although the latter itself is not a perfectoid ring. In fact, there is no final object in Perfd. As we will see, this is a feature rather than a bug.

**Analogy 1.2.6.** Sanath will talk about the details about FF curves. For now, let us be satisfied by the following:

	$Global\ Geometric\ Langlands$	Geometrized Local Langlands
	$for\ functional\ field$	
geometry	algebraic geometry over $\mathbb{F}_p$	"perfectoid geometry"
test objects	$schemes \ S \in \mathrm{Sch}_{/\mathbb{F}_p}$	$char\ p\ perfectoid\ space\ S \in \mathrm{Perfd}_p$
final test object	$\operatorname{Spec} \mathbb{F}_p$	$\mathbf{not} \ \mathbf{exist} \ \mathrm{Spa} \mathbb{F}_p \notin \mathrm{Perfd}_p$
spaces	$prestacks \supset fpqc\text{-}stacks \supset algebraic spaces$	$prestacks \supset v\text{-}stacks \supset diamonds$
absolute curve	$X \ over \mathbb{F}_p$	not exist/sci-fi
relative curve	$X_S \coloneqq S  imes_{\mathbb{F}_p} X$	$\mathcal{X}_S \coloneqq \mathcal{Y}_S / \operatorname{Frob}_S \coloneqq (S \times \operatorname{Spa} \mathbb{Q}_p) / \operatorname{Frob}_S$

Question 1.2.7. Wait, how dare you multiply a char 0 object  $\operatorname{Spa}\mathbb{Q}_p$  with a char p object S!

Warning 1.2.8. There is a dot over the product sign in the notation  $S \times \operatorname{Spa}\mathbb{Q}_p$ , which means it is not a fiber product, at least not naively. For example,  $\operatorname{Spa}(R, R^+) \times \operatorname{Spa}\mathbb{Q}_p$  is an open subspace of  $\operatorname{Spa}W(R^+)$ , where  $W(R^+)$  is the ring of p-Witt vectors in  $R^+$ . In fact, it is the open subspace where the functions  $p, [\varpi] \in W(R^+)$  are invetible, where  $\varpi \in R^+$  is a pseudo-uniformizer. Whatever this means, we see  $S \times \operatorname{Spa}\mathbb{Q}_p$  is of char 0.

Question 1.2.9. Wait, if  $\mathcal{X}_S$  is of char 0, is it okay to study it using char p test objects? For example, when talking about Hecke modifications, you need a notion of Cartier divisors of  $\mathcal{X}_S$  relative to the base, but where is your base? It can't be S or S/Frob<sub>S</sub> because they are char p.

**Answer 1.2.10.** No, at least not in the naive way. The correct way to relate  $\mathcal{X}_S$  to char p objects is via its associated diamond  $(\mathcal{X}_S)^{\diamond}$ , which we will explain now.

Construction 1.2.11 ([FS21, Sect. 6.2]). For any commutative ring R, the (p-)tilt of R is

$$R^{\flat} := \lim(\dots \xrightarrow{\operatorname{Frob}} R \xrightarrow{\operatorname{Frob}} R \xrightarrow{\operatorname{Frob}} R).$$

A priori this is only a multiplicative monoid. If R is equipped with a good enough complete topology, such as a perfectoid ring, then one can define a ring structure where the addition law is

$$(x^{(0)}, x^{(1)}, \dots) + (y^{(0)}, y^{(1)}, \dots) \coloneqq (z^{(0)}, z^{(1)}, \dots),$$

where

$$z^{(i)} := \lim_{n \to \infty} (x^{(i+n)} + y^{(i+n)})^{p^n}.$$

In particular, when R is a perfectoid ring, we obtain a char p perfectoid ring  $R^{\flat}$ . We say R is a untilt of  $R^{\flat}$ .

We define

$$\operatorname{Spd}(R, R^+) := \operatorname{Spa}(R, R^+)^{\flat}.$$

Using gluing, we can define  $X^{\flat}$  for any prefectoid space X.

**Remark 1.2.12.** For perfectoid ring R, we have  $(R^{\flat})^{\circ} \simeq (R^{\circ})^{\flat}$ .

**Example 1.2.13.** Any char p prefectoid ring R is the tilt of itself, and is the only char p untilt of itself. But there are char 0 untilts.

**Example 1.2.14.** The tilt of  $\mathbb{Q}_p^{\text{cycl}}$  is  $\mathbb{F}_p((t^{1/p^{\infty}}))$ .

**Theorem 1.2.15** (Tilting Equivalence). For any perfectoid space X, the functor  $Y \mapsto Y^{\flat}$  induces an equivalence between the categories of perfectoid spaces over X and  $X^{\flat}$ . This equivalence preserves (finite) étale covers.

**Definition 1.2.16.** For any pre-adic space X, define  $X^{\Diamond}$  to be the prestack

$$X^{\diamondsuit}: \operatorname{Perfd}_p^{\operatorname{op}} \to \operatorname{Set}, \ S \mapsto \bigsqcup_{S \notin \operatorname{Untilt}(S)} \operatorname{Maps}(S^{\sharp}, X).$$

**Theorem 1.2.17.** Whatever it means, the underlying topological spaces of X and  $X^{\diamondsuit}$  are canonically homeomorphic.

**Example 1.2.18.** Spd  $\mathbb{Z}_p := (\operatorname{Spa} \mathbb{Z}_p)^{\diamondsuit}$  classifies all untilts;  $\operatorname{Spd} \mathbb{Q}_p := (\operatorname{Spa} \mathbb{Q}_p)^{\diamondsuit}$  classifies all char 0 untilts.

**Example 1.2.19.** If X is already a perfectoid space, then  $X^{\diamondsuit} \simeq X^{\flat}$  by the tilting equivalence.

**Example 1.2.20.** For char p pre-adic space X, the functor  $X \mapsto X^{\Diamond}$  is just

$$\operatorname{PreAdic}_{p} \to \operatorname{Funct}(\operatorname{PreAdic}_{p}^{\operatorname{op}}, \operatorname{Set}) \to \operatorname{Funct}(\operatorname{Perfd}_{p}^{\operatorname{op}}, \operatorname{Set}).$$

This is because only char p untilts  $S^{\sharp}$  can map to X.

**Example 1.2.21.** By the tilting equivalence, if X is the quotient of  $R \rightrightarrows Y$  of perfectoid spaces connected by pro-étale maps, then  $X^{\diamondsuit}$  is the quotient of  $R^{\flat} \rightrightarrows Y^{\flat}$ . Essentially, diamonds are defined to be such quotients. In fact, any nalytic pre-adic space, which means all its residue fields are not discrete, over  $\mathbb{Z}_p$  can be written as such a quotient.

Remark 1.2.22. Yifei will talk about the pro-étale topology and explain why it is powerful.

**Example 1.2.23.** Unfortunately/fortunately,  $\operatorname{Spa}\mathbb{Q}_p$  is not a perfectoid space but it has a perfectoid pro-étale cover  $\operatorname{Spa}\mathbb{Q}_p^{\operatorname{cycl}} \to \operatorname{Spa}\mathbb{Q}_p$  whose Galois group is  $\mathbb{Z}_p^{\times}$ . Hence

$$\operatorname{Spd} \mathbb{Q}_p \simeq \operatorname{Spd} \mathbb{Q}_p^{\operatorname{cycl}}/\mathbb{Z}_p^{\times} \simeq \operatorname{Spa} \mathbb{F}_p((t^{1/p^{\infty}}))/\mathbb{Z}_p^{\times},$$

where  $\mathbb{Z}_p^{\times}$  is the discrete group diamond.

**Theorem 1.2.24.** For any char p perfectoid space S, we have

$$(S \times \operatorname{Spa} \mathbb{Q}_p)^{\diamondsuit} \simeq S \times \operatorname{Spd} \mathbb{Q}_p.$$

Remark 1.2.25. For a char p perfectoid space S, a map  $S \to \operatorname{Spd}\mathbb{Q}_p$  provides a char 0 until  $S^{\sharp}$ , which will provide a closed immersion  $S^{\sharp} \to \mathcal{Y}_S := S \times \operatorname{Spa}\mathbb{Q}_p$  once we know the precise definition of the target. This is a Cartier divisor and so is the composition  $S^{\sharp} \to \mathcal{X}_S$ . Also, the latter only depends on the composition  $S \to \operatorname{Spd}\mathbb{Q}_p \to \operatorname{Spd}\mathbb{Q}_p / \operatorname{Frob}$ . This suggests  $\operatorname{Spd}\mathbb{Q}_p / \operatorname{Frob}$  should be the moduli prestack of Cartier divisors on FF curves.

In fact, as we have seen (or will see) in geometric Langlands, we use  $\overline{\mathbb{F}_p}$ -points on the curve to define Hecke modifications. Hence we should restrict our attension to S defined over  $\overline{\mathbb{F}_p}$  rather than  $\mathbb{F}_p$ . The effect is to change  $\operatorname{Spd} \mathbb{Q}_p^{\operatorname{ur}}/\operatorname{Frob}$ , where  $\mathbb{Q}_p^{\operatorname{ur}}=\operatorname{Frac}(W(\overline{\mathbb{F}_p}))$  is the maximal unramified extension of  $\mathbb{Q}_p$ .

We can finally define the moduli of divisors on FF curves:

Definition 1.2.26. The moduli diamond of degree 1 closed Cartier divisors on FF curves is

$$\operatorname{Div}^1 := \operatorname{Spd} \mathbb{Q}_p^{\operatorname{ur}} / \operatorname{Frob}.$$

Warning 1.2.27. Unlike in algebraic geometry, Div<sup>1</sup> is not the curve itself. They live in different characteristics. In fact, we do not have the absolute FF curve.

**Remark 1.2.28.** An amazing thing is this tilting/untilting game allows us to consider products of the "curve", or in fact, consider  $\operatorname{Div}^1 \times \cdots \times \operatorname{Div}^1$ . Unlike the self product of  $\operatorname{Spa}\mathbb{Q}_p$ , this product, which is taken in the category of diamonds, is not boring. Lin thinks this is essentially because  $\operatorname{Perfd}_p$  lacks a final object.

1.3. Why Fargues–Fontaine curve? Please read [FS21, Sect. I.11] (titled "The origin of the ideas"). For now, let me explain how the automorphic and Galois sides naturally appear in this geometrization picture.

For the Galois side:

Theorem 1.3.1.  $\pi_1(\text{Div}^1) \simeq W_E$ .

**Remark 1.3.2.** Heuristically this follows from the definition  $\operatorname{Div}^1 := \operatorname{Spd} \mathbb{Q}_p^{\operatorname{ur}} / \operatorname{Frob}$ . Indeed,  $W_E$  is the extension of  $\mathbb{Z}(\operatorname{Frob})$  by  $\operatorname{Gal}(\overline{\mathbb{Q}_p}/\mathbb{Q}_p^{\operatorname{ur}})$ .

Question 1.3.3. Wait, didn't you say FF curves behaved like genus 0 curves?

**Answer 1.3.4.** Yes. But  $\mathcal{X}_{\mathcal{C}}$  is not defined over  $\mathcal{C}$  or any algebraically closed field. Instead, we have:

Theorem 1.3.5.  $\Gamma(\mathcal{X}_C, \mathcal{O}) \simeq \mathbb{Q}_p$ .

For the automorphic side, we consider the v-stack  $\operatorname{Bun}_G$  whose values  $\operatorname{Bun}_G(S)$  classify G-torsors on  $\mathcal{X}_S$ . Taeuk will explain the precise meaning of the following:

**Theorem 1.3.6.** Bun<sub>G</sub> has a stratification labelled by the poset B(G) such that each stratum is of the form \*/H, where H is a group diamond which is an extension of a discrete group  $M(\mathbb{Q}_p)$  by a unipotent group, where M is an inner form of a Levi subgroup of G.

Corollary 1.3.7. For any  $\mathbb{Z}_l$ -algebra  $\Lambda$ , the category  $D(\operatorname{Bun}_G, \Lambda)$  can be glued from categories  $\operatorname{Rep}(M(\mathbb{Q}_p))$  for M being inner forms of Levi subgroups of G.

Yifei will explain how to define  $D(-,\Lambda)$  and play with them.

## 1.4. What can be translated from Geometric Langlands?

**Answer 1.4.1.** Essentially any pure geometric constructions in Geometric Landlands can be or at least should be translated. Things already done in [FS21]: geometric Satake, Lafforgue's automorphic-to-Galois construction via shitukas, formulation of categorical Langlands conjecture, the spectral action...

1.5. What else? The story is not complete without talking about p-adic Hodge theory. After all, FF curves were born during the study of Fontaine's peroid rings.
